(54) Tibe: METHOD OF SEQUENCING DNA BASED ON THE DETECTION OF THE RELEASE OF PYROPHOSPHATE

(57) Abstract

The present inversion provides a method of identifying a base at a target position in a sample DNA sequence wherein an extension priner, which hybridizes to the sample DNA immediately adjacent to the larget position is provided and the sample DNA and extrassion priner are subjected to a polymerase reaction in the presence of a decrynuclostide or dideoxynuclostide whereby the deoxynuclostide or dideoxynuclostide will only become incorporated and release proposphate (PP) if it is complementary to the base in the target position, any release of PP1 being detected enzymically, different deoxynuclostides (PP) if it is complementary to the base in the target position, any release of PP1 being detected enzymically, different deoxynuclostides being added either to separate aliques of sample-primer mixture or successively to the same sample-primer relature and subjected to the polymerase reaction step, such that unincorporated nucleotides are degraded.

This invention relates to a method of sequencing DNA, based on the detection of base incorporation by the release of pyrophosphate (PPi) and simultaneous enzymatic nucleotide degradation.

as scanning tunnel electron microscopy (Driscoll et al., several alternative strategies have been described, such electrophoretic methods for sequencing is great and disadvantages of electrophoresis. Struct. Dynamics, 7, 301-306), to overcome the 1990, Nature, 346, 294-296), sequencing by hybridization high throughput are needed. Thus, the need for nonsequencing where relatively cost-effective units with suited for large-scale genome projects or clinical commercially available, electrophoresis is not well fragments are cumbersome procedures, a great effort has well as the subsequent detection of the separated DNAaccording to their size, DNA fragments produced from a the chemical cleavage technique of Maxam and Gilbert. are the enzymatic chain-termination method of Sanger and The two most commonly used methods for DNA sequencing the large genomes of humans and other higher organisms. nucleotide sequences has become increasingly important genetic analysis. The ability to determine DNA single molecule detection (Jeff et al., 1989, Biomol (Bains et al., 1988, J. Theo. Biol. 135, 308-307) and fact that automated electrophoresis units are been made to automate these steps. However, despite the Both methods rely on gel electrophoresis to resolve, as efforts have commenced to determine the sequences of larger DNA segment. Since the electrophoresis step as DNA sequencing is an essential tool in molecular

Techniques enabling the rapid detection of a single DNA base change are also important tools for genetic

analysis. In many cases detection of a single base or a few bases would be a great help in genotic analysis since several genetic diseases and certain cancers are related to minor mutations. A mini-sequencing protocol based on a solid phase principle was described (Hultman, et al., 1988, Nucl. Acid. Res., 17, 4937-4946; Syvanen et al., 1990, Genomics, 8, 684-692). The incorporation of a radiolabeled nucleotide was measured and used for analysis of the three-allelic polymorphism of the human apolipoprotein E gene. However, radioactive methods are not well suited for routine clinical applications and hence the development of a simple non-radioactive method for rapid DNA sequence analysis has also been of interest.

Methods of sequencing based on the concept of detecting inorganic pyrophosphate (PPi) which is released during a polymerase reaction have been described (WO 93/23564 and WO 89/09283). As each nucleotide is added to a growing nucleic acid strand during a polymerase reaction, a pyrophosphate molecule is released. It has been found that pyrophosphate released under these conditions can be detected enzymically e.g. by the generation of light in the luciferase-luciferin reaction. Such methods enable a base to be identified in a target position and DNA to be sequenced simply and rapidly whilst avoiding the need for electrophoresis and the use of harmful radiolabels.

However, the PPI-based sequencing methods mentioned above are not without drawbacks. The template must be washed thoroughly between each nucleotide addition to remove all non-incorporated deoxynucleotides. This makes it difficult to sequence a template which is not bound to a solid support. In addition new enzymes must be added with each addition of deoxynucleotide.

Thus, whilst PPi-based methods such as are described above do represent an improvement in case and speed of operation, there is still a need for improved

methods of sequencing which allow rapid detection and and quick to perform, lending themselves readily to provision of sequence information and which are simple

automation.

and detected, as each nucleotide is incorporated. permit the sequencing reactions to be continuously method of the invention may also readily be adapted to and as will be discussed in more detail below, the new there is no need to immobilise the DNA. Conveniently, example in a single microtitre plate. Advantageously, the procedure to be carried out simply and rapidly, for performed without intermediate washing steps, enabling and which permits the sequencing reactions to be sequencing method in which these problems are addressed monitored in real-time, with a signal being generated We now propose a novel modified PPi-based

nucleotides are degraded. that, a nucleotide-degrading enzyme is included during dideoxynucleotide is incorporated, characterised in polymerase reaction to indicate which deoxynucleoside or same sample-primer mixture and subjected to the aliquots of sample-primer mixture or successively to the or dideoxynucleotides being added either to separate being detected enzymically, different deoxynucleotides the base in the target position, any release of PPi release pyrophosphate (PPi) if it is complementary to dideoxynucleotide will only become incorporated and dideoxynucleotide whereby the deoxynucleotide or in the presence of a deoxynucleotide or extension primer are subjected to a polymerase reaction target position is provided and the sample DNA and hybridises to the sample DNA immediately adjacent to the sample DNA sequence wherein an extension primer, which a method of identifying a base at a target position in a the polymerase reaction step, such that unincorporated In one aspect, the present invention thus provides

The term "nucleotide-degrading enzyme" as used

Sigma Chemical Company. Other suitable nucleotide and Pi is phosphate). Apyrase may be obtained from nucleoside diphospate, NMP is a nucleotide monophosphate a nucleoside diphosphatase and triphosphatase, degrading enzyme is essential for the invention. the phosphate group, for example at the base or nucleoside degrading activity may be used, e.g. enzymes other NTP degrading activity is present. Although enzymes are described in the literature. <u>al</u>., 1980, J. Biol. Chem., 255, 1227-1233). Further nucleoside triphosphate diphosphohydrolase (Le Bel et triphosphate degrading enzymes include Pig Pancreas Pi (where NTP is a nucleoside triphosphate, NDP is a catalysing the reactions NTP - NMP + 2Pi and NTP - NDP such enzymes include most notably apyrase which is both nucleoside tri-phosphate degrading enzyme. Suitable are optional and may be used in combination with a Nucleoside di- and/or mono-phosphate degrading enzymes sugar residues. Thus, a nucleoside criphosphate invention, any enzyme having any nucleotide or nucleotide-degrading enzymes having a phosphatase enzymes, provided that a nucleoside triphosphatase or phosphates, and any mixture or combination of such triphosphates (NTPs), but optionally also di- and monodegrading nucleotides, including at least nucleoside herein includes all enzymes capable of non-specifically which cleave nucleotides at positions other than at activity may conveniently be used according to the

degradation, eg. different Km, different efficiencies degradation step in any given system. combinations of nucleotide degrading enzymes may be for a different nucleotides etc. Thus, different have different characteristics for deoxynucleotide described in the literature and different enzymes may monophosphatases may be used. Such enzymes are used, to increase the efficiency of the nucleotide Different combinations of nucleoside tri-, di- or For example, in

Advantageously all nucleotides may be degraded to a further nucleoside triphosphate is added. In such a diphosphates remaining to nucleoside triphosphates, when di- and monophosphatases. nucleosides by the combined action of nucleoside tri-, disphosphatase to degrade the nucleoside diphosphates. case, it may be advantageous to include a nucleoside with kinases which may convert any nucleoside some cases, there may be a problem with contamination

or enzymes are simply included in the polymerase of the procedure. Thus, the nucleotide-degrading enzyme procedure to proceed without washing the template example, if desired the K, of the nucleotide-degrading efficiently incorporated by the polymerase, and then any is selected to have kinetic characteristics relative to 0.25 U/mL to 2 U/mL. enzyme apyrase may conveniently be used in amounts of The amount of nucleotide-degrading enzyme to be used, substantially most of the unincorporated nucleotides. reaction mix, and a sufficient time is allowed between each new nucleotide addition, thus improving the economy advantage is that since washing steps are avoided, it is between successive nucleotide additions. A further polymerase are degraded. This allows the sequencing that nucleotides which are not incorporated by the enzyme may be higher than that of the polymerase such non-incorporated nucleotides are degraded. Thus, for the polymerase such that nucleotides are first depending on the reactants selected, reaction conditions readily be determined for each particular system, and the length of time between nucleotide additions may each successive nucleotide addition for degradation of not necessary to add new enzymes eg. polymerase with Generally speaking, the nucleotide-degrading enzyme However, it has for example been found that the

enzyme(s) may be included during the polymerase reaction As mentioned above, the nucleotide-degrading

- 7 -

activity may be boosted by adding immobilised enzyme as described above.

The term dideoxynucleotide as used herein includes all 2'-deoxynucleotides in which the 3'-hydroxyl group is absent or modified and thus, while able to be added to the primer in the presence of the polymerase, is unable to enter into a subsequent polymerisation reaction.

PPi can be determined by many different methods and a number of enzymatic methods have been described in the literature (Reeves <u>et al</u>., (1969), Anal. Biochem., 28, 282-287; Guillory <u>et al</u>., (1971), Anal. Biochem., 39, 170-180; Johnson <u>et al</u>., (1968), Anal. Biochem., 15, 273; Cook <u>et al</u>., (1978), Anal. Biochem. 91, 557-565; and Drake <u>et al</u>., (1979), Anal. Biochem. 94, 117-120).

It is preferred to use luciferase and luciferin in combination to identify the release of pyrophosphate since the amount of light generated is substantially proportional to the amount of pyrophosphate released which, in turn, is directly proportional to the amount of base incorporated. The amount of light can readily be estimated by a suitable light sensitive device such as a luminometer.

Luciferin-luciferase reactions to detect the release of PPi are well known in the art. In particular, a method for continuous monitoring of PPi release based on the enzymes ATP sulphurylase and luciferase has been developed by Nyrén and Lundin (Anal. Biochem., 151, 504-509, 1985) and termed EMIDA (Enzymatic Luminometric Inorganic Pyrophosphate Detection Assay). The use of the ELIDA method to detect PPi is preferred according to the present invention. The method may however be modified, for example by the use of a more thermostable luciferase (Kaliyama <u>ct. al.</u>, 1994, Biosci. Biotech. Biochem., 58, 1170-1171) and/or ATP sulfurylase (Onda <u>ct. al.</u>, 1996, Bioscience, Biochemistry, 60:10, 1740-42). This

WO 98/28440 PCT/GB97/03518

·

' အ

method is based on the following reactions:

ATP sulphurylase

PPi + APS ------ ATP + SO,

luciferase

ATP + luciferin + O<sub>2</sub> ------ AMP - PPi +

oxyluciferin + CO<sub>2</sub> + hv

APS = adenosine 5'-phosphosulphate)

The preferred detection enzymes involved in the PPi detection reaction are thus ATP sulphurylase and luciferase.

The method of the invention may be performed in two steps, as described for example in WO93/23564 and WO89/09283, firstly a polymerase reaction step ie. a primer extension step, wherein the nucleotide(s) are incorporated, followed by a second detection step, wherein the release of PPi is monitored or detected, to detect whether or not a nucleotide incorporation has taken place. Thus, after the polymerase reaction mix may be removed and analysed by the ELIDA eg. by adding an aliquot of the sample to a reaction mixture containing the ELIDA enzymes and reactants.

However, as mentioned above, the method of the invention may readily be modified to enable the sequencing (ie. base incorporation) reactions to be continuously monitored in real time. This may simply be achieved by performing the chain extension and detection, or signal-generation, reactions substantially simultaneously by including the "detection enzymes" in the chain extension reaction mixture. This represents a departure from the approach reported in the PPI-based sequencing procedures discussed in the literature above, in which the chain extension reaction is first performed

9

separately as a first reaction step, followed by a separate "detection" reaction, in which the products of the extension reaction are subsequently subjected to the luciferin-luciferase based signal generation ("detection") reactions. This "real time" procedure represents a preferred embodiment of the invention.

or they may be added with the reagent that initiates the already present at the time the reaction is initiated, addition of the polymerase or, more preferably the enzyme. The polymerase reaction may be initiated by dideoxy), polymerase, luciferin, APS, ATP suphurylase reaction, the reaction mix for the polymerase reaction nucleotide, and preferably the detection enzymes are and luciferase together with a nucleotide-degrading may thus include at least nucleoride (deoxy- or polymerase reaction. In the case of an ELIDA detection step prior to, simultaneously with or during the enzymes are added to the reaction mix for the polymerase chain extension reaction step. Thus the detection method of the invention, the PPi-detection enzyme(s) are included in the polymerase reaction step ie. in the To carry out this preferred embodiment of the

This latter embodiment of the present invention thus permits PPi release to be detected during the polymerase reaction giving a real-time signal. The sequencing reactions may be continuously monitored in real-time. A procedure for rapid detection of PPi release is thus enabled by the present invention. The ELIDA rections have been estimated to take place in less than 2 seconds (Nyrén and Lundín, supra). The rate limiting step is the conversion of PPi to ATP by ATP sulphurylase, while the luciferase reaction is fast and has been estimated to take less than 0.2 seconds. Incorporation rates for polymerases have also been estimated by various methods and it has been found, for example, that in the case of Klenow polymerase, complete

WO 98/28440 PCT/GB97/03518

- 10 -

incorporation of one base may take less than 0.5 seconds. Thus, the estimated total time for incorporation of one base and detection by ELIDA is approximately 3 seconds. It will be seen therefore that very fast reaction times are possible, enabling realtime detection. The reaction times could further be decreased by using a more thermostable luciferase. By using a nucleotide-degrading enzyme with a time in the order of seconds for degradation can be achieved in time frames from seconds to several minutes.

Thus, the method of the present invention may be performed in a single reaction step involving an up to 4-enzyme or more reaction mixture ie. a multi-enzyme mixture. It is surprising that a beneficial and cooperative effect between multiple interlinked enzyme reactions may take place according to the invention and yield beneficial results.

A coupled sequencing/detection system may therefore be based on the following reactions:

DNA polymerase

dNTP + (DNA), ------ (DNA), + PPi

ATP
sulfurylase
ppi ----- ATP

ATP ------ Light

Apyrase

Apyrase
ATP ------ AMP + 2Pi

11 -

It will be noted that a nucleotide-degrading enzyme such as apyrase would also degrade the ATP not used in the luciferase reactions. Thus, all nucleotide triphosphates are degraded.

Indeed, when PPI release according to the invention is detected by luciferase-based reactions e.g. ELIDA, this ATP-degrading activity may be an important advantage, particularly in "turning off" the light production by the luciferin/luciferase reaction. This may also be of advantage, with a low "burn rate" of the luciferase enzyme.

A potential problem which has previously been observed with PPi-based sequencing methods is that dATP, used in the sequencing (chain extension) reaction, interferes in the subsequent luciferase-based detection reaction by acting as a substrate for the luciferase enzyme. This may be reduced or avoided by using, in place of deoxy- or dideoxy adenosine triphosphate (ATP), a dATP or ddATP analogue which is capable of acting as a substrate for a polymerase but incapable of acting as a substrate for a said PPi-detection enzyme.

The term "incapable of acting" includes also analogues which are poor substrates for the detection enzymes, or which are substantially incapable of acting as substrates, such that there is substantially no, negligible, or no significant interference in the PPi detection reaction.

Thus, a further preferred feature of the invention is the use of a dATP or ddATP analogue which does not interfere in the enzymatic PPi detection reaction but which nonetheless may be normally incorporated into a growing DNA chain by a polymerase and can also be degraded by the nucleotide degrading enzymes. By "normally incorporated" is meant that the nucleotide is incorporated with normal, proper base pairing. In the preferred enbodiment of the invention where luciferase is the PPi detection enzyme, the preferred analogues for

WO 98/28440 PCT/GB97/03518

other nucleotides may also be used in place of all luciferase system resulting from dATP interference is with the polymerase may be achieved while the background that substituting dATP with dATPoS allows efficient substantially decreased. The dNTPoS analogues of the signal due to the generation of light by the luciferinability of dATP to function as a substrate for dATP, which eliminates the background caused by the increased by using a nucleotide analogue in place of  $dATP\alpha S$  and luciferase. The signal-to-noise ratio is signal due to the absence of an interaction between from New England Nuclear Labs. Experiments have shown thio analogues of dCTP, dGTP and dTTP, may be purchased thio]criphospate, or deoxyadenosine α-thiotriphosphate deoxy or dideoxy ATP, preferably deoxyadenosine [1thio)triphosphate (or a-thiotriphosphate) analogues of luciferase. In particular, an efficient incorporation incorporation by the polymerase with a low background  $(dATP\alpha S)$  as it is also known.  $dATP\alpha S$ , along with the  $\alpha$ use according to the invention are the [1-

The sample DNA (ie. DNA template) may conveniently be single-stranded, and may either by immobilised on a solid support or in solution. The use of a nucleotide-degrading enzyme according to the present invention means that it is not necessary to immobilise the template DNA to facilitate washing, since a washing step is no longer required. By using thermostable enzymes, double-stranded DNA templates might also be used.

The sample DNA may be provided by any desired source of DNA, including for example PCR or other amplified fragments, inserts in vectors such as M13 or plasmids.

In order to repeat the method cyclically and thereby sequence the sample DNA and, also to aid separation of a single stranded sample DNA from its complementary strand, the sample DNA may optionally be

nuclectide(s) may be achieved by chain extension using the target DNA. The identification of the terminal identifying one or more nucleotides at the terminus of the method of the present invention. repeated. Sequence information is obtained by target DNA. The ligation and cleavage cycle is then nucleotides from the ligation site, leaving a shortened complex at a site within the target DNA, one or more nuclease recognition site to a double stranded target stranded probe (or adaptor) containing a Class IIS Such methods generally involve ligating a double 5,599,675 and Jones, BioTechniques 22: 938-946, 1997). targets, based on ligation of probes or adaptors and advantageously permitting sequencing of double-stranded example, a number of iterative sequencing methods, applicability in other methods of sequencing. For (sample) DNA and cleaving the probe/adaptor-target subsequent cleavage have been described (see e.g. US-A-The method of the invention may also find

nucleotide. Use of a strand-displacing polymerase 677-679. In such a method the sample DNA may be by Fu et al., in Nucleic Acids Research 1997, 25(3): by the introduction of nicks, for example as described the present invention. the 3' end of probe/adaptor at the nick, nucleotide permits a sequencing reaction to take place by extending sequence which serves to introduce a nick e.g. by sequencing protocol based on strand displacement, e.g. incorporation being detected according to the method of containing a non- or mono-phosphorylated or dideoxy modified by ligating a double-stranded probe or adaptor DNA, the method of the invention may be used in a Further to permit sequencing of a double stranded

which provide a permanently attached 3' primer at the 3' WO93/23563 which uses PCR to introduce loop structures invention may be combined with the method taught in Advantageously, the method according to the present

and/or extension reactions use the hybridised portion as permitted or caused to hybridise to region A, thereby amplified double-stranded DNA is subjected in end of the target sequence, in the following order, the substantially identical to A, said amplification target sequence while having at its 5'-end a sequence second primer having a 3'-terminal sequence which sequence, which first primer is immobilised or provided 3'-terminus of the sequence complementary to the target 3' from region A, whereby said double-stranded DNA is and there being optionally a DNA region B which extends onto a target sequence of one strand of double stranded immediately adjacent the target position. The dideoxy forming said loop. The 3' end of region A' hybridises immobilised target strand is liberated and region A' is immobilised form to strand separation whereby the nonsequence A' complementary to sequence A, whereafter the region A, a region capable of forming a loop and a producing double-stranded target DNA having at the 3'hybridises to at least a portion of A and/or B of the with means for attachment to a solid support, and a amplification using a first primer hybridising to the subjected to polymerase chain reaction (PCR) sequence having a region A at the 3'-terminus thereof DNA which contains the target position, said target introduced as part of the 3'-terminal loop structure such a modified method, the extension primer is terminal of a DNA strand of interest. For example, in

the ELIDA as described previously. The PPi formed in DNA polymerase catalyzed primer extension is measured by concept relies on the measurement of the difference in the polymerization reaction is converted to ATP by ATF matched over a mismatched 3' terminal. The rate of the primer extension efficiency by a DNA polymerase of a real-time detection of known single-base changes. This The method of the invention may also be used for

> By performing the assay in the presence of a nucleotide template a high extension rate will be observed. In polymerase and deoxynucleotides, measured with the complementary to the non-mutated DNA-sequence and the monitored by the firefly luciferase. In the single-base extend, such as A:T, T:G and C:T. match and a mismatch of the type that are easy to degrading enzyme. It is easier to distinguish between a natural deoxynucleotide after the 3'-mismatch termini. the  $\alpha$ -thiotriphosphate analog for the next correct efficiencies may be strongly decreased by substituting non-mutated sequence. The relative mismatch extension the mutated DNA sequence can be distinguished over the matched over a mismatched 3'-terminal can then be used primer extension efficiency by the DNA polymerase of a extension rate will be much lower. The difference in exactly match to the template (mismatch) the primer contrast, if the 3'-end of the detection primer does not SLIDA. If the detection primer exactly matches to the extension rates are, after incubation with DNA termini over the base of interest and the primer sequence. The primers are hybridized with the 3'other precisely complementary to the mutated DNAbase at the 3'~end are designed; one precisely as template. Two detection primers differing with one detection assay, single-stranded DNA fragments are used sulfurylase and the ATP production is continuously for single-base discrimination. Thus, the presence of

methods of the invention which will normally include at least the following components: The invention also comprises kits for use in

- <u>e</u> a test specific primer which hybridises to sample DNA so that the target position is directly adjacent to the 3' end of the primer;
- 9 a polymerase;

29

(c) detection enzyme means for identifying pyrophosphate release;

- (d) a nucleotide-degrading enzyme.
- deoxynucleotides, or optionally deoxynucleotide analogues, optionally including, in place of dATP, a dATP analogue which is capable of acting as a substrate for a polymerase but incapable of acting as a substrate for a said PPi-detection enzyme; and
- (f) optionally dideoxynucleotides, or optionally dideoxynucleotide analogues, optionally ddATP being replaced by a ddATP analogue which is capable of acting as a substrate for a polymerase but incapable of acting as a substrate for a said ppi-detection enzyme.

If the kit is for use with initial PCR amplification then it will also normally include at least the following components:

- a pair of primers for PCR, at least one primer having means permitting immobilisation of said primer;
- (ii) a polymerase which is preferably heat stable, for example Taql polymerase;
- (iii) buffers for the PCR reaction; and
- (iv) deoxynucleotides

The invention will now be described by way of a non-limiting Example with reference to the drawings in which:

Figure 1 is a schematic representation of a new DNA sequencing method of the invention. The four different nucleotides are added stepwise to the template hybridised to a primer. The PPi released in the DNA polymerase catalysed reaction, is detected by the ATP sulfurylase and luciferase catalysed reactions. The height of the signal is proportional to the number -of bases which have been incorporated. The added nucleotides are continuously degraded by a nucleotide degrading enzyme. After the first added nucleotide is degraded, the next nucleotide can be added. These steps are repeated in a cycle and the sequence of the template is deduced;

Figure 2 shows DNA sequencing on a 35-base long oligonucleotide template. About 2 pmol of the template/primer (E3PN/NUSPT) were incubated with 4 pmol (exo<sup>-</sup>) Klenow and 0.2 U apyrase. The reaction was started by the addition of 0.4 nmol of each of the indicated deoxynucleotides and the PPi released was detected in real-time by the ELIDA. The DNA-sequence of the template is shown in the Figure. The experimental conditions are as described in Example 1.

Figure 3 shows DNA sequencing on a 35-base-long oligonucleotide template. About 5 pmol of the template/primer (B3PN/NUSPT) were incubated with 8 pmol (exo) Klenow and 0.2 U apyrase. The reaction was started by the addition of 0.4 nmol of the indicated deoxynucleotide and the PPi released was detected by the ELIDA. The DNA-sequence of the template is shown in the Figure. The experimental conditions were as described in Example 1.

Figure 4 shows DNA sequencing on a 35-base-long oligonucleotide template. About 5 pmol of the template/primer (PEBE25/RIT27) were incubated with 8 pmol (exo') Klenow and 0.2 U apyrase. The reaction was started by the addition of 0.4 nmol of the indicated deoxynucleotide and the PPi released was detected by the

PCR reactions were performed on the multilinker of plasmid pRT 28 with 7.5 pmol of general primers, RIT 28 and RIT 29 (biotinylated), according to Hultman et al. (supra). The biotinylated PCR products were immobilised onto streptavidin-coated super paramagnetic beads Dynabeads<sup>TM</sup> M280-Streptavidin, or M450-Streptavidin (Dynal, A.S., Oslo, Norway). Single-stranded DNA was obtained by removing the supernatant after incubation of the immobilised PCR product in 0.10 M NaOH for 5 minutes. Washing of the immobilised single-stranded DNA and hybridization to sequencing primers was carried out as described earlier (Nyrèn et al., 1993, Anal. Biochem. 208, 171-175).
